Cryptographic Hash Functions

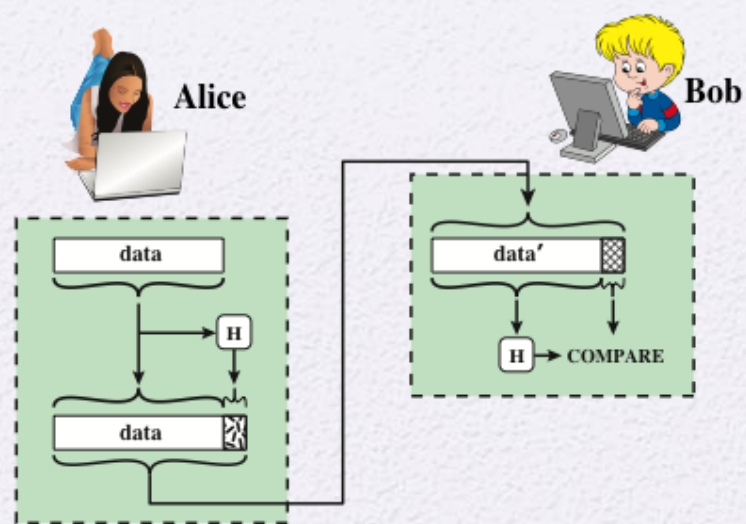

Hash Functions

- A hash function H accepts a variable-length block of data M as input and produces a fixed-size hash value
 - $h = H(M)$
 - Principal object is data integrity
- Cryptographic hash function
 - An algorithm for which it is computationally infeasible to find either:
 - (a) a data object that maps to a pre-specified hash result (the one-way property)
 - (b) two data objects that map to the same hash result (the collision-free property)

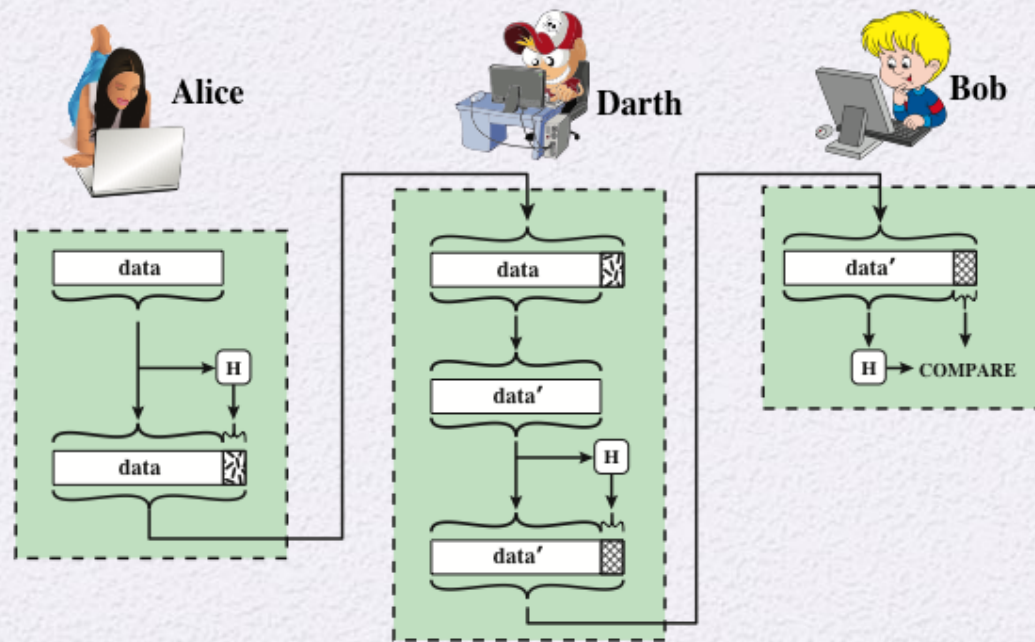

P, L = padding plus length field

Figure 11.2 Attack Against Hash Function

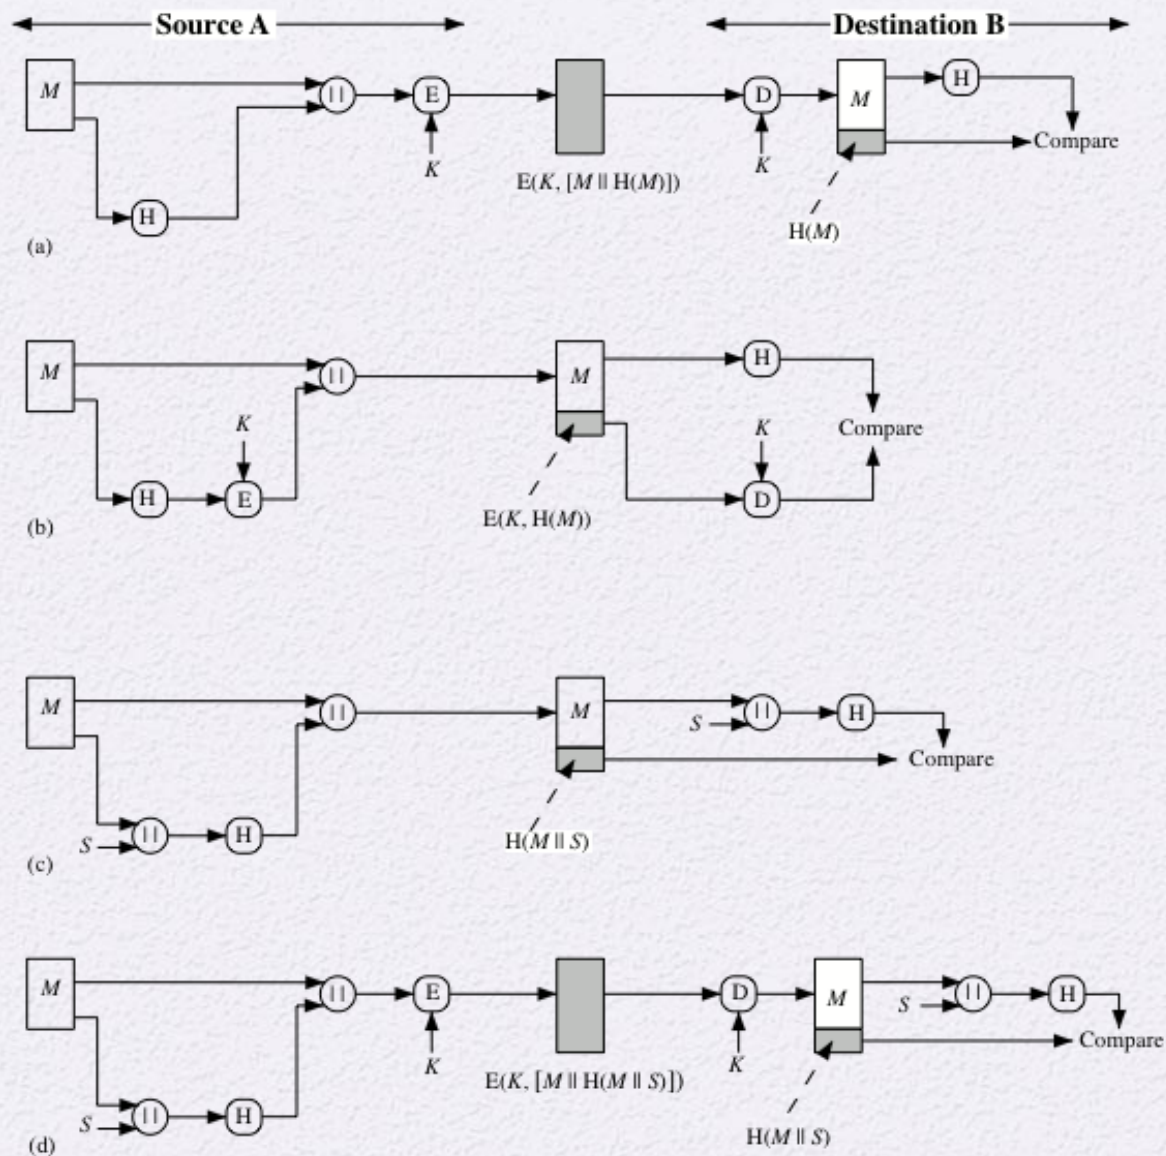

Figure 11.3 Simplified Examples of the Use of a Hash Function for Message Authentication

Message Authentication Code (MAC)

- Also known as a *keyed hash function*
- Typically used between two parties that share a secret key to authenticate information exchanged between those parties

Takes as input a secret key and a data block and produces a hash value (MAC) which is associated with the protected message

- If the integrity of the message needs to be checked, the MAC function can be applied to the message and the result compared with the associated MAC value
- An attacker who alters the message will be unable to alter the associated MAC value without knowledge of the secret key

Digital Signature

- Operation is similar to that of the MAC
- The hash value of a message is encrypted with a user's private key
- Anyone who knows the user's public key can verify the integrity of the message
- An attacker who wishes to alter the message would need to know the user's private key
- Implications of digital signatures go beyond just message authentication

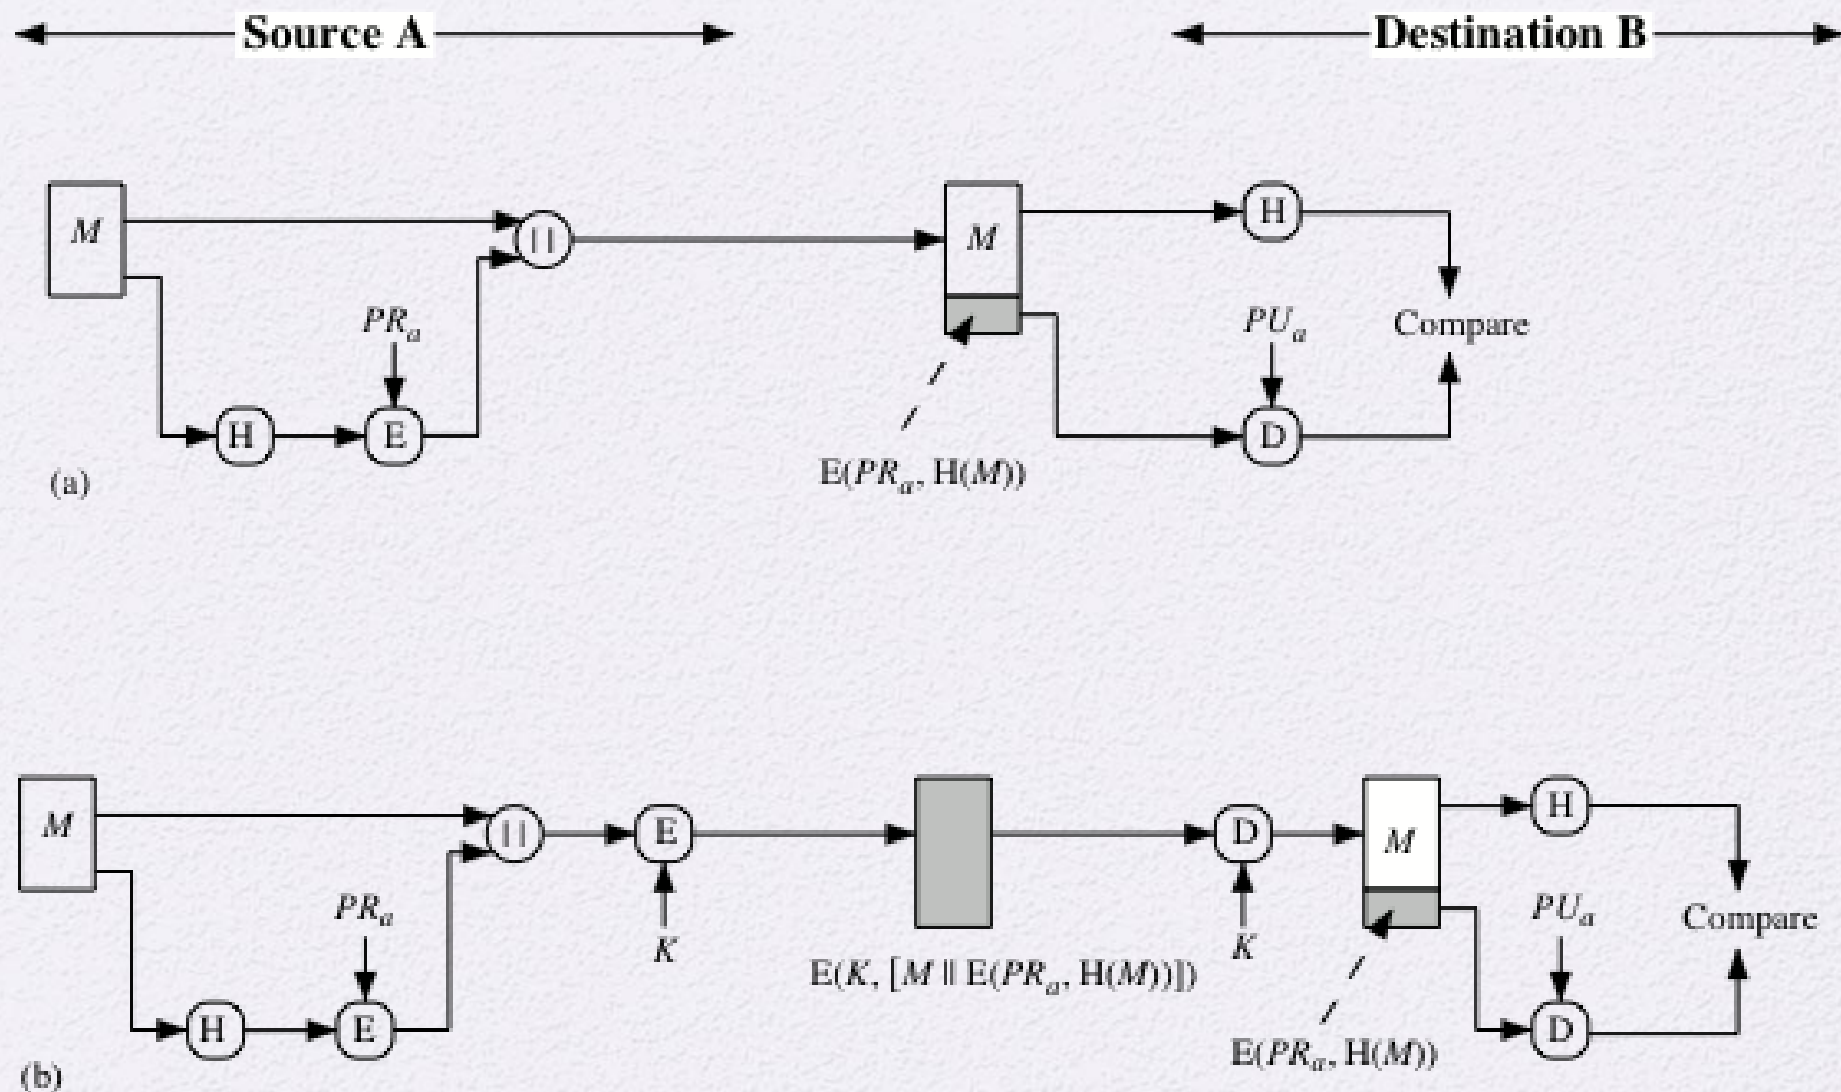

Figure 11.4 Simplified Examples of Digital Signatures

Other Hash Function Uses

Commonly used to create a one-way password file

When a user enters a password, the hash of that password is compared to the stored hash value for verification

This approach to password protection is used by most operating systems

Can be used for intrusion and virus detection

Store $H(F)$ for each file on a system and secure the hash values

One can later determine if a file has been modified by recomputing $H(F)$

An intruder would need to change F without changing $H(F)$

Can be used to construct a pseudorandom function (PRF) or a pseudorandom number generator (PRNG)

A common application for a hash-based PRF is for the generation of symmetric keys

Requirements and Security

Preimage

- x is the preimage of h for a hash value $h = H(x)$
- Is a data block whose hash function, using the function H , is h
- Because H is a many-to-one mapping, for any given hash value h , there will in general be multiple preimages

Collision

- Occurs if we have $x \neq y$ and $H(x) = H(y)$
- Because we are using hash functions for data integrity, collisions are clearly undesirable

Table 11.1

Requirements for a Cryptographic Hash Function H

Requirement	Description
Variable input size	H can be applied to a block of data of any size.
Fixed output size	H produces a fixed-length output.
Efficiency	$H(x)$ is relatively easy to compute for any given x , making both hardware and software implementations practical.
Preimage resistant (one-way property)	For any given hash value h , it is computationally infeasible to find y such that $H(y) = h$.
Second preimage resistant (weak collision resistant)	For any given block x , it is computationally infeasible to find $y \neq x$ with $H(y) = H(x)$.
Collision resistant (strong collision resistant)	It is computationally infeasible to find any pair (x, y) such that $H(x) = H(y)$.
Pseudorandomness	Output of H meets standard tests for pseudorandomness

Attacks on Hash Functions

Brute-Force Attacks

- Does not depend on the specific algorithm, only depends on bit length
- In the case of a hash function, attack depends only on the bit length of the hash value
- Method is to pick values at random and try each one until a collision occurs

Cryptanalysis

- An attack based on weaknesses in a particular cryptographic algorithm
- Seek to exploit some property of the algorithm to perform some attack other than an exhaustive search

Collision Resistant Attacks

- For a collision resistant attack, an adversary wishes to find two messages or data blocks that yield the same hash function
 - The effort required is explained by a mathematical result referred to as the *birthday paradox*
 - In essence, if we choose random variables from a uniform distribution in the range 0 through $N - 1$, then the probability that a repeated element is encountered exceeds 0.5 after \sqrt{N} choices have been made.
- Yuval proposed the following strategy to exploit the birthday paradox in a collision resistant attack:
 - The source (A) is prepared to sign a legitimate message x by appending the appropriate m -bit hash code and encrypting that hash code with A's private key
 - Opponent generates $2^{m/2}$ variations x' of x , all with essentially the same meaning, and stores the messages and their hash values
 - Opponent prepares a fraudulent message y for which A's signature is desired
 - Opponent generates minor variations y' of y , all of which convey essentially the same meaning. For each y' , the opponent computes $H(y')$, checks for matches with any of the $H(x')$ values, and continues until a match is found. That is, the process continues until a y' is generated with a hash value equal to the hash value of one of the x' values
 - The opponent offers the valid variation to A for signature which can then be attached to the fraudulent variation for transmission to the intended recipient
 - Because the two variations have the same hash code, they will produce the same signature and the opponent is assured of success even though the encryption key is not known

Random Oracle Model

- Notion of an idealized hash function
- Random Oracle model is a model in which all parties (including adversaries) have oracle (black-box) access to a consistent, uniformly random function

$$\text{RO} : \{0, 1\}^* \rightarrow \{0, 1\}^n$$

- This oracle can be thought of as choosing a random output y on being queried with a value x and remembering its choice.
- When two people query the function with the same x , they both receive the same y value.

Random Oracle Model...

- For a hash code of length m , the level of effort required, as we have seen, is proportional to the following:
 - Preimage resistant: 2^m
 - Second preimage resistant: 2^m
 - Collision resistant: $2^{m/2}$

Merkle-Damgard Iterated Hash Function: Idea

Figure 11.8 General Structure of Secure Hash Code

Hash Functions Based on Cipher Block Chaining

- Divide a message M into fixed-size blocks M_1, M_2, \dots, M_N and use a symmetric encryption system such as DES to compute the hash code G as
$$H_0 = \text{initial value}$$
$$H_i = E(M_i, H_{i-1})$$
$$G = H_N$$
- Similar to the CBC technique, but in this case, there is no secret key
- As with any hash code, this scheme is subject to the birthday attack
- If the encryption algorithm is DES and only a 64-bit hash code is produced, the system is vulnerable

Secure Hash Algorithm (SHA)

- SHA was originally designed by the National Institute of Standards and Technology (NIST) and published as a federal information processing standard (FIPS 180) in 1993
- Was revised in 1995 as SHA-1
- Based on the hash function MD4 and its design closely models MD4
- Produces 160-bit hash values
- In 2002 NIST produced a revised version of the standard that defined three new versions of SHA with hash value lengths of 256, 384, and 512
 - Collectively known as SHA-2

SHA-3

SHA-1 has not yet been "broken"

- No one has demonstrated a technique for producing collisions in a practical amount of time
- Considered to be insecure and has been phased out for SHA-2

NIST announced in 2007 a competition for the SHA-3 next generation NIST hash function

- Winning design was announced by NIST in October 2012
- SHA-3 is a cryptographic hash function that is intended to complement SHA-2 as the approved standard for a wide range of applications

SHA-2 shares the same structure and mathematical operations as its predecessors so this is a cause for concern

- Because it will take years to find a suitable replacement for SHA-2 should it become vulnerable, NIST decided to begin the process of developing a new hash standard
